CHAPTER 1

Reliability and Validity

The purpose of this chapter is to provide the reader a high-level and illustrative summary of the evidence to support the reliability and validity of the dimensions of the Situational Outlook Questionnaire® (SOQ). Information about these attributes of the SOQ is provided to introduce you to the instrument, explain how it operates and illustrate the soundness of the measure. If you are already familiar with the behavioral sciences, then you already know about the importance of these attributes. If you are new to this area, it may be helpful to point out why it is important to present this kind of information.

Table 1
Approaches to Assessment

If you examine Table 1 above, you can see that there are many different approaches to assessment. Our colleague, Dr. Don Treffinger frequently shared this two-by-two matrix with his graduate students to illustrate this point. It is possible to focus on providing very limited information and have a measure that is very easy to use. This is identified as expedience in the matrix.

The kind of assessment that is expedient includes those measures you can pick up at the grocery store that include five items and they try to tell you if you will have a good life. They are easy to complete, but provide very limited information. It is also possible to provide very little useful information and have a measure that is very difficult to use. This is referred to as self-abuse. These are the kinds of

measures that have many items, and take a long time to complete, but only provide very limited information. A third possibility is to have a measure that provides a great deal of useful information and is very easy to use. This is referred to as fantasyland in the matrix above, because it is highly unlikely that any measure that provides a high level of useful information can actually do so in a “quick and dirty” way. The fourth quadrant in the matrix is where a measure provides a great deal of useful information and has a degree of rigor to it. It is more likely that any measure or assessment that provides the user with a rich amount of useful information and insight will be relatively harder to administer, score and develop.

The basic tension in the matrix runs between those who desire a “quick and dirty” measure, and those who tend toward “rigor mortis.” Usually the proponents of the quick and dirty end of the tension include practitioners with little patience or interest in science, theory, or conceptual foundations. Academics and researchers are often found at the other end of the spectrum, some of whom have little interest in things practical. As with most things, the truth and best position is somewhere between the two absolute end points.

The reason we believe it is important to present information about the psychometric properties, reliability and validity of the SOQ is that the measure does provide a great deal of useful information. Further, it has been developed over a fifty-year period of research and development. Anyone who wishes to use the SOQ needs to be aware of the support for the measure, as well as its limitations. Further, anyone who wishes to apply the measure to organizational improvement and development, leadership development, or the improvement of teamwork, needs to be thoroughly familiar with the standards that exist for such an assessment.

When it comes to measurement in the behavioral sciences (and most other sciences), there are two fundamental characteristics for which those who use quantitative measures look. These are reliability and validity (see Pedhazur & Schmelkin, 1991).

Reliability

Reliability refers to the consistency or stability of a measure from one use to the next, with different sets of equivalent items, or under other variable examining conditions. In other words, does the measure assess what it is designed to assess consistently? The concept of reliability underlies the computation of the error of measurement of a single score. Reliability refers to the degree to which scores are free from errors of measurement. Understanding the reliability of a measure enables us to predict the range of fluctuation likely to occur in a single individual’s score as a result of irrelevant or chance factors. In its broadest sense, reliability indicates the extent to which individual differences in test scores are attributable to “true” differences in the characteristics under review and the extent to which they are attributable to chance errors or error variance (Anastasi, 1988).

Table 2
Fundamentals of Measurement

VALIDITY
<ul style="list-style-type: none">• Degree to which an instrument actually measures the construct it purports to measure
RELIABILITY
<ul style="list-style-type: none">• Degree to which an instrument consistently measures the construct

No single observation truly represents a person or climate. To know how trustworthy a measure is, we examine the consistency among administrations. There are many reasons why scores could be inconsistent. The amount of participant attention or concentration may change from moment to moment. Over longer periods of time scores can change due to physical growth, learning, changes in health and personality, as well as other factors.

A high level of reliability is a required ingredient for any measure that can be considered useful for research or practice. A measure that is reliable can be used with confidence in most settings or time periods. The use of a measure that has a low level of reliability is useless for purposes of carrying out research or for designing change in organizations. Decisions and conclusions that are drawn from measures that have low levels of reliability are built on the types of chance and randomness that typically result in failure. Erroneous and unfavorable decisions, which are unjust, disruptive and damaging, can result when they are influenced by temporary variations in performance or by the choice of questions included on a measure (Cronbach, 1984).

Finally, reliability is a necessary but not a sufficient condition for validity. In other words, a measure cannot be valid if it is not reliable.

Kinds of Reliability

There could be as many varieties of test reliability as there are sources for variation and conditions affecting test scores (Anastasi, 1988). The level of a measure's reliability is assessed through a variety of statistical techniques. The two most common categories of reliability are known as consistency over time and internal consistency.

Consistency over time is derived from the correlation of the scores from subjects who took the instrument and then took it again at a later point in time. The main question addressed is: "How likely is it that I will get a similar result when I take this measure again?" The span of time from the first administration to the second can range from weeks to months and is generally known as test-retest

reliability. If the correlations between the subjects' first and second score are greater than .70, the instrument is generally considered reliable over time.

Table 3
Forms of Reliability

CONSISTENCY OVER TIME

- Test-retest reliability

INTERNAL CONSISTENCY

- Split-half or odd-even method
 - Kuder-Richardson formula
 - Cronbach's alpha
-

The second form of reliability is known as internal consistency. This kind of reliability addresses the question of how items within the measure consistently relate to each other and the dimensions to which the items belong. The main question is “How well do the items or dimensions hold together?” It is usually derived from three common statistical techniques. The techniques most commonly used are the: 1) Split-half or odd-even method, 2) Kuder-Richardson formula, and 3) Cronbach's alpha. Each of these techniques only requires that the subjects take the instrument once. The methods are briefly explained in the glossary of this manual or can be further explained within any book on statistics. Like the first form of reliability, consistency over time, if the instrument receives a value greater than or equal to .70 it is generally considered to be internally reliable. Since a measure of climate assesses a “state” set of variables, rather than “trait” variables considering internal reliability is an important aspect for both research and practice.

Validity

Validity refers to the accuracy of a measure. In other words, does the measure truly assess what it was designed to assess? Reasonable levels of validity are required for any measure. It determines the extent to which the measure is useful for both research and practice. A measure that is valid provides accurate information that can be used to guide both research and practice. The use of a measure that has limited validity is highly questionable for purposes of carrying out research or for implementing change in organizations. Decisions and conclusions that are drawn from sources that have questionable validity are built on shaky ground and therefore may be doomed to fail.

The nature of a measure's validity is established over time; a single study is not sufficient in scope to establish the validity of a measure. Rather, it takes a series of investigations that approach the question of validity from different angles to establish the accuracy of a particular measure. In addition,

the SOQ has been derived from the CCQ, a measure that has a great deal of evidence including numerous doctoral dissertations and dozens of published studies. In respect to the SOQ, numerous studies have been carried out, and are being presently carried out, to examine its validity. Other technical resources have provided a summary of some of the work that has explored various aspects of the SOQ's validity. Most of the studies cited in these previous sections used earlier versions of the SOQ (i.e., CCQ IA, CCQ IIA, CIQ IIIA).

The issue of validity of any measure is very different than that of reliability. In a way, reliability is an easier issue in that it relies primarily on mathematics. Validity, on the other hand, often requires judgment and insight. In addition, there is no clear consensus on the meaning of forms of validity.

There are no fixed rules for deciding what high levels of validity are versus low levels of validity. Studying a measure's validity can be primarily based on logic (face or content), or based on statistics or empirical examination (construct or a criterion-related form of validity like concurrent, predictive or criterion-related).

Table 4
Forms of Validity

CONSTRUCT VALIDITY

- Does the inventory measure what it intends to measure?

PREDICTIVE VALIDITY

- Does the measure predict future performance?

CONTENT VALIDITY

- Does the inventory assess the domain it claims to measure?

CONCURRENT VALIDITY

- Is the inventory related to other valid measures of the same construct?
-

Forms of Validity (The 1985 Standards)

There are various forms of validity. These were put forward by an earlier version of the Standards for Educational and Psychological Tests (1985). One of the "lightest" forms is called face validity. This typically means that the items, dimensions or scales look appropriate. Most researchers would call face validity the least important indicator of a measure's soundness or adequacy.

Construct validity involves an effort to understand the meaningfulness of the instrument and the rationale that lies behind the measure. It attempts to answer the question: Does the assessment measure what it is intended to measure? When it comes to construct validity, there may be no natural

criterion upon which to claim validity for a measure. For many, construct validity refers to the entire body of accumulated evidence surrounding a measure.

Content validity is concerned with the degree to which a measure represents knowledge or behaviors from the domain it purports to measure. According to Jaeger (1990) content validity is not determined through statistical procedures, but is assessed on the basis of sound judgment. In order to assess the content validity of a measure, the content (items, dimensions, scales, etc.) are examined in detail. Some of the ways to examine content validity include Q-sort methods, inter-subjective verification of items, etc. For example, the items within a creative climate measure should be able to be reviewed and classified by reasonably informed groups and should cluster onto the theoretical dimensions. Further, the specific dimensions measured by a creative climate assessment should have support in the published scientific literature on the topic.

Predictive validity is sometimes also referred to as criterion validity, particularly when the focus is on how well scores on one measure relate to some other criterion measure.

When this kind of validity is high, we can use the scores on one measure to predict performance on the criterion variable. Evidence for this form of validity is usually gained by producing a validity coefficient (a correlation between the scores on the measure and a specified criterion). A creative climate measure should be able to predict the level of job satisfaction, reduced levels of work-related stress, increased levels of creative productivity, etc.

Concurrent validity is when a measure demonstrates a clear and significant relationship with another measure for which there is some evidence of validity. If one measure of the climate for creativity can correlate significantly with another measure of climate that has already shown some evidence of validity we can claim concurrent validity for the first measure.

Evidence of Validity (The 1999 Standards)

The new standards published for educational and psychological tests have revised the terminology associated with validity (American Educational Research Association, American Psychological Association, & the National Council on Measurement in Education, 1999). The new terms are designed to reflect the point of view that validity is not something to be “typed.” Instead, there are different lines of validity evidence. As a result, this section will use the more current terminology.

These lines of evidence include:

- Evidence based on test content – an analysis on the relationship between a test’s content and the construct it is intended to measure.

- Evidence based on response processes – the analysis of response processes concerning the fit between the construct and the detailed nature of performance or response in which respondents engage.
- Evidence based on internal structure – analysis of the internal structure of a test indicating the degree to which the items conform to the construct.
- Evidence based on relations to other variables – analysis of the relationship of test scores to variables external to the test.

Ultimately, any user of an assessment needs to be concerned about the usability of the measure. Of course, there is no point in using a measure unless we can have some confidence in its results, but at some point a user must consider its functional or application potential. Usability is concerned with a number of practical issues. Once the user is satisfied that there is sufficient reliability and validity evident, attention must be focused on how long it takes to complete the measure, how easily it is scored and interpreted, the cost of the assessment, etc.

When you think about answering the question: What is a “good” assessment, you will need to know that it makes sense and that it works. Making sense is often a matter of having clear definitions of the concepts that are based on solid frameworks and theory. Having tight definitions provide the borders of the measure so that you know what it assesses, and what it does not assess. Knowing that a measure works is based on how reliable and valid it is, as well as how useful and helpful it is.

CHAPTER 2

A Summary of the Evidence

The Situational Outlook Questionnaire® (SOQ) is based on clear conceptual foundations and has been the subject of continuous research and development for more than 50 years. This means that the SOQ has more than adequate evidence regarding its reliability and validity. The purpose of this chapter is to provide a representative summary of this evidence.

Evidence of SOQ's Reliability

Reliability refers to the stability or consistency of a measure from one use to the next (test-retest) or the stability of the measure itself (internal reliability). Below you will find a representative listing of research findings for consistency over time and the internal consistency of the SOQ.

Consistency over Time

- A longitudinal study of a product development project in a high-tech company was conducted across a three-year period with the climate being measured every three months. The results showed that the dimensions possessed good reliability using aggregated scores.
- Similar comparisons using the current version of SOQ show good reliability using aggregated scores. Specifically, four different groups of respondents within one global organization took the SOQ as a part of the leadership development initiative over seven months. There were no significant differences in their assessment of the same organization over time.

Internal Reliability

Internal consistency is a measure of precision and deals with how items are related to its own scale rather than to other scales. This is also referred to as internal reliability. We would want the dimensions of the SOQ to be relatively stable over time, as well as have the items consistently correlate with their respective scales.

- The results of analysis with the Scandinavian precursor (CCQ) show very high levels of internal consistency for the version translated into English.

- Analysis for previous versions of the SOQ reports ranges of Cronbach's Alphas: .52-.90; Guttman split-half: .54-.86; and Spearman Brown: .57-.89.
- Analysis for the current version of SOQ reports Cronbach's Alpha ranges for 8 of the 9 dimensions from .79 - .89, which exceeds the accepted criteria of .70 for internal consistency. Trust/Openness is the only dimension not to fall into this range with a reported alpha of .69 - very close to the standard of .70.

Consistency of Format

- Substantial correlations were found between the paper and web-based version of the SOQ. Analysis of Variance on these results showed no significant differences between results from either form of the measure.

Evidence of SOQ's Validity

Validity refers to the accuracy of a measure. A variety of kinds of evidence can and should be collected to support the validity of any measure. The list below summarizes many of the more detailed findings presented in the other technical resources.

Evidence based on test content

Evidence based on test content includes an analysis on the relationship between a test's content and the construct it is intended to measure.

- A comprehensive study of the climate literature focusing on the 50 most pertinent works provided evidence for all the dimensions of the SOQ.
- Multiple Q-sort studies conducted also provide support that the SOQ's items and dimensions measure the domain they are designed to assess.
- Comparison of R&D departments with different kinds of innovation (adaptive or incremental versus innovative and radical) using the dimensions of the SOQ have shown predictable and clear differences.
- Research on best-practice versus normal practice research and development teams has shown the dimensions of the SOQ discriminate between these types of teams.
- Studies on quality of care in primary care centers and day-homes for children have shown that the dimensions of the SOQ have picked up on observed differences.

- Dimensions of the SOQ have demonstrated relationships that sort groups based on their number and kind of rewards given for effective performance on the job.

Evidence based on response processes

Evidence based on response processes includes the analysis of response processes concerning the fit between the construct and the detailed nature of performance or response in which respondents engage.

- Studies to ensure that the dimensions of the SOQ are measuring an organizational attribute, rather than an individual one, have shown consistent significant discrimination among multiple departments within a large industrial company.
- Research studies of patterns of interaction in work-groups – offensive and defensive action – routines, show appropriate and significant correlations between dimensions of the SOQ and perceived patterns of interaction.
- Multiple studies examining the relationship between individual psychological climate (using the SOQ) and other distinct constructs of cognitive style (KAI), problem solving style (VIEW), and psychological type (MBTI) show few modest correlations. This provides support that the interpersonal domain of climate is distinct from the intrapersonal domain of style.
- Comparison studies of various divisions or subsidiaries within organizations has shown that the dimensions of the SOQ can and do discriminate among them; particularly when considering factors relating to creativity, innovation and change.
- The SOQ has been able to discriminate the nature of the working environment between magnet (those having more discretion) and non-magnet hospitals.

Evidence based on internal structure

Evidence based on internal structure includes analysis of the internal structure of a test indicating the degree to which the items conform to the construct.

- Consistent examination of multiple exploratory factor analyses on all versions of the SOQ have shown an increasingly clear factor structure that shows the items of the measure falling on their respective dimensions.
- Confirmatory factor analysis with 225 samples of convenience (N = 7,345) resulted in a GFI of 0.88, an AGFI of 0.87, an NFI of 0.89, and a RMSEA of .047, indicating an adequate fit of the nine-dimensional model.

Evidence based on relations to other variables

Evidence based on relations to other variables includes analysis of the relationship of test scores to variables external to the test.

Dimensions of the SOQ show significant correlations with a number of effect (dependent) variables including:

- Warr's Well-Being Scales, having to do with psychological well-being
- Job-satisfaction
- Sources of Pressure in Your Job (SPIYP), a measure of occupational stress
- Survey of Creative and Innovative Performance (SCIP), a measure of creative productivity and kinds of creative products developed
- Numbers of patents produced
- Numbers of suggestions contributed to suggestion systems

Dimensions of the SOQ show significant correlations with a number of antecedent variables including:

- Organizational Value Scales (multiple studies)
- Leadership Style
- Innovation Strategy

Dimensions of the SOQ show significant correlations with:

- Work Environment Scale, assessing related social factors at work.
- Scales on the Work Environment Inventory (WEI-later named KEYS), another commercially available measure of the work environment for creativity.
- Organizational Value Scales (multiple studies), showing the significant relationship between values relating to structure, people and development and the dimensions assessed by the SOQ.
- Multi-method research comparing the quantitative and qualitative portions of the SOQ have shown confirmatory support for the dimensions of climate.

- Research using Nystrom’s method for determining the level of innovation of organizations has shown clear and significant differences on all SOQ dimensions between innovative and stagnated organizations.
- Dimensions of the SOQ clearly separate people’s perceptions of the best and worst work environments.
- Dimensions of the SOQ demonstrate clear and significant differences between people’s perceptions of their most and least creative teamwork experiences.
- The SOQ shows significant correlations with measures of employee recognition for making new contributions to the organization.
- The SOQ demonstrates statistically significant ability to discriminate on measures of perceived support for creativity on the job.
- The SOQ demonstrates the ability to significantly discriminate levels of leadership support for creating an environment that supports innovation.
- The SOQ demonstrates the ability to significantly discriminate levels of success with both incremental and radical innovation.
- The SOQ demonstrates the ability to significantly discriminate levels of empowerment for making decisions locally (within the meaningful and proximal work unit) about innovation.
- The SOQ demonstrates the ability to significantly discriminate the degree to which people consider consumer insight and needs more than technology push in innovation efforts.
- The SOQ demonstrates the ability to significantly discriminate levels of uncertainty avoidance in the workplace.
- The SOQ demonstrates the ability to significantly discriminate levels of support for implementing new ideas within work units and overall success with innovation.
- The SOQ demonstrates the ability to significantly discriminate the degree to which people in an organization believe in and promote both diversity and inclusion.

Usability

Usability is concerned with a number of practical issues. Once the user is satisfied that there is sufficient reliability and validity evident, attention must be focused on how long it takes to complete the measure, how easily it is scored and interpreted, the cost of the assessment, etc.

Over 50 years of inquiry into the dimensions that capture the perceived patterns of behavior that characterize the work-life and psychosocial environment that supports creativity, innovation, and change has resulted in rather substantial evidence of reliability and validity. The SOQ, along with its Scandinavian precursor, has also demonstrated high levels of usefulness and practical utility for those who lead and manage organizations.

The SOQ has been applied within hundreds of organizations to help them assess their readiness and ability to develop a work environment that supports creativity, innovation and change. More recently, the SOQ has been successfully applied to help cross-functional teams assess their work environment and to help leaders better understand their role in creating a climate that engages and enables people.

Over the years, the dimensions have weathered a variety of versions, statistical evaluations, and structural modifications all designed to improve their accuracy and precision as tools to improve the working climate for creative productivity in all sorts of organizations. The next, and final, chapter in this section outlines the kinds of research and development that will help continue this journey.

CHAPTER 3

Alternative Benchmarks

A benchmark is a standard by which something can be measured or judged. The hope is that by using specified standards better comparisons can be made in order to make improvements. The earliest, and most widely applied climate benchmarks have been the work done by Göran Ekvall to illustrate the differences between innovative and stagnated organizations. This work was done during the 1980's and 1990's so some people may discount their value, but we have continued to examine the dimensions and have quite a few additional benchmarks you can use to help your clients.

Innovative and Stagnated Organizations

Ekvall collaborated with Harry Nyström on a unique program of research. They applied a comprehensive innovation audit on 30 international organizations and were able to clearly differentiate those organizations that were innovative (they invested in new products that increase the likelihood of long-term survival and commercial success) from those that were stagnated (unsuccessful in creating new products and experienced troubled commercial performance).

These are the most widely used benchmarks to compare the innovative with the stagnated climates within organizations. They provide clear directionality for the SOQ dimensions that has been supported by many more recent studies. They can help those who receive their SOQ results decide upon which dimensions to focus. The emphasis should be upon their own strategy and conditions rather than using these benchmarks as "absolutes."

Leadership Support of Innovation

Participants were asked to respond to an additional question when completing the SOQ. The question was: Leaders and managers I observe are effective in creating an environment that supports innovation. The Akkermans study included 140 participants from 103 companies and 31 industries, Retz included 180 participants from aerospace engineering, and the Adolfsen study included 57 participants from Volvo and Wärtsilä.

Most and Least Creative Teams

Participants in a global professional services organization were asked to identify their most and least creative team experience before completing a short form of the SOQ. The definition provided to them regarding the most creative team was one that produced something that was: new, unique, or original; valuable, relevant and useful; and accepted, produced results, and made a positive impact. The least creative team was described for them as one that produced something that was: well within previous practice or standard, where they “reinvented the wheel;” useless or valueless; and was rejected or produced very little or no impact.

Best and Worst Case Workplaces

Two studies examined the differences in people's perceptions of the climate in their best and worst-case work experiences. Participants reflected on their previous work experiences and were given the following written instructions: "The purpose of this questionnaire is to examine your experience working in a situation you would consider to be the most supportive of your creativity. From your memory of that 'best case' situation, please rate that environment on the following statements by circling the appropriate number on the scale below the statement." Similar instructions phrased for "least supportive" and "worst-case" were provided on another form. To ensure that the participants had a clear retrospective focus, they were asked to write down a description of the specific work situation before completing the climate assessments.

Perceived Support of Creativity

The relationship between mean ratings of the nine dimensions that make up the Situational Outlook Questionnaire and the self-perception of the organizational climate as conducive (or not conducive) to creativity was tested with a sample of 1,830 individuals from a variety of organizations. Participants were categorized on their level of perceived support for creativity. The results indicated that the means of all nine dimensions of the Situational Outlook Questionnaire were different for each level of perceived support for creativity in the work environment. The difference was statistically significant for each level. The results of this study indicated that the Situational Outlook Questionnaire is able to discriminate effectively among different levels of perceived support for creativity in the immediate work environment.

Uncertainty Avoidance

Three hundred thirty-four employees of a global pharmaceutical company were surveyed as a part of a global innovation audit. A question was added to the full SOQ to determine the extent to which employees tended to avoid innovation projects filled with ambiguity. This question is negatively framed, so that lower scores on it should reflect more positive climate scores (as they do).

Citation:

Isaksen, S. G., & Isaksen, E. J. (2010). *The climate for creativity and innovation: And its relationship to empowerment, consumer insight, and ambiguity*. A technical report from the Creativity Research Unit of the Creative Problem Solving Group, Inc.

Note: Uncertainty avoidance has to do with a natural bias against creativity. See:

Mueller, J. S., Melwani, S., & Goncalo, J. A. (2012). The bias against creativity: Why people desire but reject creative ideas. *Psychological Science*, 23, 13-17.

Successful Implementation of New Ideas

For the purposes of this study, the SOQ was modified to include an additional question to assess the level of proximal innovation. The question was: We are successful in implementing new ideas to obtain results in my work unit. The aim of this question was to assess the level of success with innovation within the more immediate working climate.

Magnet and Non-Magnet Hospitals

The SOQ was applied to study nurses' perceptions of climate in magnet versus non-magnet Veterans Administration hospitals. Nurses in magnet hospitals experience more empowerment, better support for clinical decision-making, and better patient outcomes. Hospitals that achieve magnet status must demonstrate compliance with standards of care and professional performance.

Belief in Diversity

An SOQ intervention was undertaken in 2010 at a large American university. The total sample was 525 individuals across a wide variety of roles in the university. One of the main focuses of the intervention was to gauge their diversity and inclusion efforts. This allowed CPSB to also look into the relationships between these efforts and the perceived climate for creativity and innovation. The additional question was: “People here believe the staff is diverse.”

Table 18

Work Engagement

This study applied the SOQ and the Utrecht Work Engagement Scale with 95 employees of a major Ministry in Bergen, Norway. All dimensions of the SOQ correlated significantly with work engagement, with Challenge and Involvement having the highest r value of .71 ($p < .0001$). Regression analysis showed that higher scores on Challenge and Involvement and slightly lower scores on Debate were good predictors of engagement ($B = .831$; $F = 50.63$, $p < .0001$).

Level of Collaboration

This study applied the SOQ and a collaborative relationship survey with 222 employees working in the third-part logistics industry. Collaboration was defined as occurring when two or more independent companies work jointly to plan and execute operations with greater success than when acting alone (Nyaga, Whipple, & Lynch, 2010). Collaborative relationships stress an exchange of information, knowledge, complementary resources and capabilities, and relational asset specific investments (Klein & Rai, 2009).

Effectiveness of Talent Development

A credit union service organization contacted a total of 651 participants from 11 Credit Unions and one CUSO. A total of 497 returned complete questionnaires that were included in our analysis (76.3% response rate). We collected the data between June of 2018, and November of 2019. The majority of participants (78.3%) responded in 2019. The participating individuals represented credit unions across the United States (Florida, Wisconsin, Washington DC) and Canada and from all levels of staff (22.1% of the respondents were working in middle- or upper-level management positions in the respective credit unions). We developed and applied a scale including 6 items to assess talent development effectiveness.

Dimension	Mean			F	p	η^2
